This article has been cited by other articles in PMC. Introduction In , head and neck squamous cell carcinoma HNSCC had an estimated incidence of 48, cases 11, deaths within the U. Over HPV types are known; these are classified as low- or high-risk based on their association with cervical carcinoma. This variability may be attributable to: Unlike the striking association with oropharyngeal cancers, the incidence of HPV in other head and neck sites remains unclear. Medical records were examined to obtain detailed clinical and histopathological information, including age, sex, disease site, histopathological diagnosis, disease stage, history of tobacco and alcohol use, nodal metastasis, treatment, and outcome. Subsets of patients were classified as social or rare alcohol drinkers as written in their clinical reports. Patients having no use of tobacco or alcohol within one year prior to surgery were classified as former smokers and drinkers, respectively. The median age was 59 range, years of age. The male-female ratio was approximately 2: Median follow up time was 22 months range, months. Tumor samples and DNA isolation The 92 samples used in this study were retrospectively collected between Tissues were snap frozen and stored in liquid nitrogen. DNA was isolated following fresh frozen tissue homogenization in liquid nitrogen using a cold steel mortar and pestle. Cases that were HPV positive were repeated, without the presence of a positive control, to verify results and exclude the risk of contamination. Statistical methods Descriptive statistics were examined as median and range for continuous variables, and frequencies and proportions for categorical variables. Overall survival was calculated using the Kaplan-Meier method. A Cox Proportional Hazard regression model was applied for continuous predictors. Statistical analyses were performed using the SAS 9. Of these, 53 were from sites in the oral cavity: The oropharyngeal cases were selected for comparison, as these tumors have a higher incidence of HPV infection.

4: Principles and Practice of Head and Neck Surgery and Oncology - CRC Press Book

Squamous cell carcinoma of the nasopharynx is usually recognized late in the course of the disease (). Often the first indication of a nasopharyngeal tumor is a fixed neck node.4 The position of this tumor at the base of the skull, surrounded by a rich lymphatic plexus, allows multiple paths for metastasis.

5: Association of Two Brm Promoter Polymorphisms With Head and Neck Squamous Cell Carcinoma Risk

Squamous cell carcinoma of the hypopharynx and cervical esophagus usually presents in the late-middle-aged and elderly. When diagnosed in young adults, the disease process is often thought to be.
