Microsoft Learn The new Microsoft Learn site provides new hands-on learning and training opportunities to Microsoft developers. New Microsoft Graph Notifications use Project Rome to offer a people-centric, cross-platform notifications platform for your app. This means that you can enhance the look, feel, and functionality of your existing desktop applications with the latest Windows 10 UI features that are only available via UWP controls, such as Windows Ink and controls that support the Fluent Design System. This feature is called XAML islands. We provide several ways to use XAML islands in your applications, depending on the application platform you are using. WPF and Windows Forms applications can use a set of controls in the Windows Community Toolkit that provide a designer-oriented development experience. For more information, see UWP controls in desktop applications. Although we encourage you to try them out in your own prototype code now, we do not recommend that you use them in production code at this time.

Windows Machine Learning Windows Machine Learning has now officially launched, providing features like faster evaluation and support for cutting-edge machine learning models. To support developers who want to integrate it into their applications, we have created a new documentation site with several new and updated resources: Windows Mixed Reality Developers can now request hardware-protected backbuffer textures if supported by the display hardware, allowing applications to use hardware-protected content from sources like PlayReady. Hardware protection support and setting is available for the primary layer by using new properties of Windows. HolographicCamera , and for Quad layers via Windows. On-Screen Keyboard The on-screen keyboard for IoT devices now uses the same touch keyboard components as the desktop edition of Windows. This enables features such as dictation mode, IME support, and a full set of input scopes. Title bars for sign-in dialogs Windows 10 IoT Core now provides the option to configure title bars for system dialog boxes. Update The new Windows. Update namespace enables interactive control of system updates. This namespace is only available for Windows 10 IoT Core. With this, you can monitor and modify navigations, track state across navigations, monitor navigation errors, and run code before views are activated. We have also written several new topics, including: Explains what WebVR is, why you should use it, and how to get started developing for it. The open-source MSIX format preserves the functionality of existing packages, while enabling modern deployment features. It can be run in the command line, or via its interactive UI. This tool is included in the Windows 10 SDK and can be used from a command prompt or a script file. For desktop applications, see Package a desktop application manually.

Try the Performance troubleshooter The first thing that you can try is the Performance troubleshooter, which can automatically find and fix problems. Open the Performance troubleshooter by clicking the Start button , and then clicking Control Panel. In the search box, type troubleshooter, and then click Troubleshooting. Under System and Security, click Check for performance issues. Even if your PC is older, it might contain manufacturer-installed programs that you never noticed or have since forgotten about. Maybe you thought you might use the software someday, but never did. Uninstall it and see if your PC runs faster. Limit how many programs run at startup Many programs are designed to start automatically when Windows starts. Decide for yourself if you want a program to run at startup. But how can you tell what programs run automatically at startup? Sometimes this is obvious, because the program adds an icon to the notification area on the taskbar, where you can see it running. Point to each icon to see the program name. Even after you check the notification area, you might still miss some programs that run automatically at startup. AutoRuns for Windows, a free tool that you can download from the Microsoft website, shows you all of the programs and processes that run when you start Windows. You can stop a program from running automatically when Windows starts by opening the AutoRuns for Windows program, and then by clearing the check box next to the name of the program you want to stop. AutoRuns for Windows is designed for advanced users. Defragment your hard disk Fragmentation makes your hard disk do extra work that can slow down your computer. Disk Defragmenter rearranges fragmented data so your hard disk can work more efficiently. Disk Defragmenter runs on a schedule, but you can also defragment your hard disk manually. Clean up your hard disk Unnecessary files on your hard disk take up disk space and can slow down your computer. Disk Cleanup removes temporary files, empties the Recycle Bin, and removes a variety of system files and other items that you no longer need. If you find your PC slowing down, ask yourself if you really need to keep all your programs and windows open at once. Running more than one antivirus program can also slow down your computer. Turn off visual effects If Windows is running slowly, you can speed it up by disabling some of its visual effects. It comes down to appearance versus performance. Would you rather have Windows run faster or look prettier? You can choose which visual effects to turn off, one by one, or you can let Windows choose for you. There are 20 visual effects you can control, such as the transparent glass look, the way menus open or close, and whether shadows are displayed. To adjust all visual effects for best performance: In the search box, type Performance Information and Tools, and then, in the list of results, click Performance Information and Tools. Click Adjust visual effects. Restart regularly This tip is simple. Restart your PC at least once a week, especially if you use it a lot. Restarting a PC is a good way to clear out its memory and ensure that any errant processes and services that started running get shut down. Restarting closes all the software running on your PC— not only the programs you see running on the taskbar, but also dozens of services that might have been started by various programs and never stopped. Restarting can fix mysterious performance problems when the exact cause is hard to pinpoint. The more things you have open and the longer you keep them running, the greater the chances your PC will bog down and eventually run low on memory. But no discussion of how to make Windows run faster would be complete without mentioning that you should consider adding more random access memory RAM to your PC. The best way to speed it up is to add more. For optimal performance, boost that to 3 GB or more. This feature allows you to use the storage space on some removable media devices, such as USB flash drives, to speed up your computer. Before you worry too much, check your PC using antispyware and antivirus programs. A common symptom of a virus is a much slower-than-normal computer performance. Other signs include unexpected messages that pop up on your PC, programs that start automatically, or the sound of your hard disk constantly working. You can check for spyware with Windows Defender or other antispyware programs. The best way to deal with viruses is to prevent them in the first place. Always run antivirus software and keep it up to date. The Windows Experience Index rates your

computer on five key components and gives you a number for each, as well as an overall base score. This base score is only as good as your worst-performing component subscore. Base scores currently range from 1 to 7. If your PC is rated lower than 2 or 3, it might be time to consider a new PC, depending on what tasks you want to do with your computer. Windows sets the initial minimum size of the paging file equal to the amount of random access memory RAM installed on your computer, and the maximum size equal to three times the amount of RAM installed on your computer. If you see warnings at these recommended levels, then increase the minimum and maximum sizes.

Some clarifications that you requested: I am upgrading computers for better hardware. The older computer which had no issues had USB 2. The new computer only has USB 3. Both my new computer and old computer are using the same USB Host controller. Both computers are using the latest Windows build as referenced in my earlier note. When I run this on my new laptop, I get a scary message: I believe that this is the cause of my problems. My old computer shows no issues when I run the same troubleshooter. As suggested, I have switched the computer power mode to higher performance and unchecked the power saving option. In the driver property settings. Method 1 shows no change to the status of the computer. I went through each of the suggestions that you listed below in Method 2 and 3. Here are my updates: The attempts to update the drivers under the Device Manager resulted in no change. It states that the latest drivers are currently installed. No improvement from Method 2 Method 3: The driver verifier says that all of the existing drivers are signed. There are no unsigned drivers present. It found none, so it appears that all of the drivers are built for the current windows version. No improvement from Method 3 Asus Tech Support: I have contacted Asus Technical support and submitted a support request. They have not gotten back to me yet. Asus also provides a software update utility in the Asus bloatware package. I have run this and there are no updates. I did that but it did not fix the issue. Please let me know if you have other suggestions. I really appreciate your support! Did this solve your problem?
