Chapter 3 – Principles of Imaging Techniques Fluoroscopy Fluoroscopy utilizes live x-rays to visualize anatomic structures. The live x-ray beam is activated by the radiologist performing the procedure. It is best utilized for examinations that depict active physical properties such as intestinal peristalsis or swallowing. The image quality in fluoroscopy is controlled by multiple x-ray detectors in the table that adjust the x-ray dose based upon the size and thickness of the tissue being imaged. The field of view of the x-ray exposure can also be controlled to minimize unnecessary exposure of other anatomy. The image can also be magnified to enhance detection of abnormalities. An example of a fluoroscopic examination is the esophogram and upper gastrointestinal series. The patient is asked to swallow barium sulfate and gas-forming granules. The barium can be seen to move with positioning gravity and peristalsis as it moves antegrade through the digestive tract while the gas rises to the highest point of the intestinal tract based upon patient positioning. The barium and the gas help to outline the inner lining of the intestine. The live fluoroscopic x-rays visualize the motion of the barium and the gas. Cine mode images are still images captured at a rapid rate and can be viewed sequentially after storage in the PACS. This sequential viewing of the multiple images simulates a video capture. Other fluoroscopy aided examinations include arthrography, barium enema, cystourethrogram, sinus tract injections, myelography and hysterosalpingography, to name a few. The positioning of the patient is dependent on the capabilities of the patient and the exam that is to be performed. For example, when carrying out an esophogram, the best positioning would be an upright standing patient and an oblique or lateral view of the anatomy to watch the barium proceeding down the esophagus. Additional oblique and lateral views allow one to visualize abnormalities in multiple planes and to determine if any abnormality of the intestinal mucosa is concealed by swallowed barium on one view. If aspiration of ingested fluid or food into the lungs is clinically suspected the lateral projection allows one to determine if fluids are entering the trachea during swallowing. They can also be displayed as standard x-rays if this advantageous for interpretation, see the barium enema images. The principles of absorption and transmission of the x-rays is unchanged, but the images are digitally manipulated to be the inverse of x-rays, much like film negatives in photography. The effect of image inversion for Fluoroscopy images is depicted in Figure 3. Images are very often inverted compared to conventional x-ray images Often use barium sulfate and gas-forming granules as contrast Examples of Fluoroscopic procedures includes:
