Giacomelli: La forma dentro.; Fotografie by Carli, Enzo. Charta, Paperback. Near new, fresh unused condition, covers bright, text clean & binding tight.

Up to table sources can be used in a statement, although the limit varies depending on available memory and the complexity of other expressions in the query. Individual queries may not support up to table sources. Query performance may suffer with lots of tables referenced in a query. Compilation and optimization time is also affected by additional factors. The order of table sources after the FROM keyword does not affect the result set that is returned. Is the name of a table or view. An alias is frequently a shortened table name used to refer to specific columns of the tables in a join. If the same column name exists in more than one table in the join, SQL Server SQL Server requires that the column name be qualified by a table name, view name, or alias. No se puede utilizar el nombre de la tabla si se ha definido un alias. The table name cannot be used if an alias is defined. Specifies that the query optimizer use an optimization or locking strategy with this table and for this statement. Es un alias opcional para sustituir el nombre de una columna en el conjunto de resultados. Is an optional alias to replace a column name in the result set. Specifies a table-valued function. Proporciona una vista de un conjunto de filas en un documento XML. Provides a rowset view over an XML document. Is a subquery that retrieves rows from the database. Is an optional alias to replace a column name in the result set of the derived table. Include one column alias for each column in the select list, and enclose the complete list of column aliases in parentheses. SQL Server Specifies that a sample of data from the table is returned. El ejemplo puede ser aproximado. The sample may be approximate. Is an implementation-dependent sampling method specified by ISO standards. SYSTEM applies a page-based sampling method in which a random set of pages from the table is chosen for the sample, and all the rows on those pages are returned as the sample subset. Is an exact or approximate constant numeric expression that represents the percent or number of rows. Indicates that the selected sample can be returned again. Se consideran cambios en la tabla las siguientes acciones: The following actions to the table are considered changes: A joined table is a result set that is the product of two or more tables. For multiple joins, use parentheses to change the natural order of the joins. Specifies the type of join operation. Specifies all matching pairs of rows are returned. Rechaza las filas no coincidentes de las dos tablas. Discards unmatched rows from both tables. When no join type is specified, this is the default. Specifies that a row from either the left or right table that does not meet the join condition is included in the result set, and output columns that correspond to the other table are set to NULL. Specifies that all rows from the left table not meeting the join condition are included in the result set, and output columns from the other table are set to NULL in addition to all rows returned by the inner join. Specifies all rows from the right table not meeting the join condition are included in the result set, and output columns that correspond to the other table are set to NULL, in addition to all rows returned by the inner join. Para mejorar el rendimiento de las consultas, puede restringir la cantidad de movimiento de datos que se produce durante el procesamiento de consultas. They can improve query performance by restricting the amount of data movement that occurs during query processing. Reduces the number of rows to be moved for the table on the right side of the join in order to make two distribution incompatible tables compatible. Causes the values in the joining column from the table on the left side of the join to be replicated to all nodes. The table on the right is joined to the replicated version of those columns. Forces two data sources to be distributed on columns specified in the JOIN clause. En el caso de una tabla distribuida, Almacenamiento de datos paralelos Parallel Data Warehouse realiza un movimiento de orden aleatorio. For a distributed table, Almacenamiento de datos paralelos Parallel Data Warehouse will perform a shuffle move. En el caso de una tabla replicada, Almacenamiento de datos paralelos Parallel Data Warehouse realiza un movimiento de recorte. For a replicated table, Almacenamiento de datos paralelos Parallel Data Warehouse will perform a trim move. This hint can improve performance when the query plan is using a broadcast move to resolve a distribution incompatible join. Indicates that the specified join operation should occur between the specified table sources or views. Specifies the condition on which the join is based. The condition can specify any predicate, although

columns and comparison operators are frequently used, for example: When the condition specifies columns, the columns do not have to have the same name or same data type; however, if the data types are not the same, they must be either compatible or types that SQL Server can implicitly convert. There can be predicates that involve only one of the joined tables in the ON clause. This is because the predicates in the ON clause are applied to the table before the join, whereas the WHERE clause is semantically applied to the result of the join. Specifies the cross-product of two tables. For more information, see the Remarks section. Is a table source as defined in the previous argument. PIVOT performs a grouping operation on the input table with regard to the grouping columns and returns one row for each group. For more information, see the Remarks section that follows. Is a system or user-defined aggregate function that accepts one or more inputs. The aggregate function should be invariant to null values. An aggregate function invariant to null values does not consider null values in the group while it is evaluating the aggregate value. Esta columna no puede ser imagen ni rowversion. This column cannot be image or rowversion. Is the alias name of the output table. Returns a table with single record for each row containing the values that were actual current at the specified point in time in the past. Internally, a union is performed between the temporal table and its history table and the results are filtered to return the values for all row versions that were active at any time during the time range specified. Rows that became active exactly on the lower boundary defined by the FROM endpoint are included and rows that became active exactly on the upper boundary defined by the TO endpoint are not included. Devuelve una tabla con los valores de todas las versiones de registro que se abrieron y cerraron dentro del intervalo de tiempo especificado definido por los dos valores de fecha y hora en el argumento CONTAINED IN. Rows that became active exactly on the lower boundary or ceased being active exactly on the upper boundary are included. Returns a table with the values from all rows from both the current table and the history table. A self-join is a table that is joined to itself. Insert or update operations that are based on a self-join follow the order in the FROM clause. PIVOT follows the following process to obtain the output result set:
