Structure definitions of documents have been used successfully for inputting and formatting in text processing systems. This report considers transformations between different representations of structured documents and studies possibilities to extend the use of structure definitions to document tra This report considers transformations between different representations of structured documents and studies possibilities to extend the use of structure definitions to document transformations and to discover algorithmic methods for carrying out transformations. Documents are presented as parse trees for context-free grammars and transformations are made from parse tree to parse tree. First, the report describes differences of manuscript styles required by various scientific journals and presents a declarative classification for structure differences between two parse trees. Second, a set of tree transformation methods are described and their suitability for transformations between documents having a structure difference in each defined class is analyzed. For each class several methods may or must be used and only certain kinds of differences can be managed automatica Proceedings of Conference on Software: Theory and Practice , " We characterize a class of structure transformations, called dense, hierarchic and local transformations, that can be eciently implemented by a two-phase, semi-automatic procedure. In the rst phase of our method, corresponding substructures are searched by an interactive procedure. In the second phase, the replacement of substructures is automatized by generating a tree transducer implementing it. Because of several storage and formatting schemes in applications, there is a need to transform the format of the documents. If the logical structure of the document is marked, it may be possible to dene an automatic transformation of the format or the structure of the document. There are various transformation systems implemented in an ad hoc manner for t Show Context Citation Context However, the syntax-directed translation is quite restricted. As XML has become a very popular standard for data in many fields, the domain of XML documents transformations is becoming more and more important. In this paper we propose classification hierarchy for XML document transformations. We assign implemented transformation systems into defined We assign implemented transformation systems into defined groups according to the type of possible transformations. This enables user to choose appropriate transformation system according to the requirements for transformation. Secondly, we are concerned with the group of transformation systems, which enable type transformation. We define underlying formal models in common framework and discuss their applicability for these transformations. There are several implemented transformation systems that are using SDTS and its modifications as underlying model. The first group - a so Many documents have a definable structure. Some document formatting systems, like the LaTeX formatter, use a structural notation. In recent years the general mark-up language SGML has gained popularity. In this work we study the transformation of a structure to another. For example, technical journa For example, technical journals have their structure definitions, and an article originally written for one journal must be restructured before it can be submitted to another journal. We assume that structure definitions are grammatical, and study what kind of transformations can be automatized or at least semiautomatized. We took a collection of computer science journals and compared their structure definitions. We classified differences as simple, local and global. As transformation techniques we studied syntax directed translation schemata and tree transducers. Our conclusion was that simple and local transformations can be automatized or semiautomatized, depending whether additional information is not needed, while global transformations are difficult to automatize. Transformations were tested in our prototype syntax-directed document processing system. The system has one module for editing a document under one structure definition, and another module for changing a document from one structure definition to another. MENTS from the user with dashed arrows. Dotted arrows describe data flows.

*"The Integrated Chameleon Architecture (ICA) is a toolset for generating data translators. In particular, the toolset can be used to generate translators to and from a constrained subset of instances of SGML DTDs. A beta release of the ICA will be available for public distribution in mid-March ().*
