This brochure was developed in Cats. Healthy breeding has been selected as a focus topic by the local host, the Danish Small Animal Veterinary Association, in light of growing concerns about the risks of inherited conditions and the welfare issues they raise for companion animals. Zorko is a specialist in canine and feline medicine and professor of veterinary radiology at the University of Ljubljana. After an initial evaluation at a local veterinary emergency room in Berkeley, Stormie, a 4-year-old female Siamese, was brought to specialists at the UC Davis veterinary hospital. Catherine Gunther-Harrington and Dr. The artery was repaired, and the doctors decided that amputation was not necessary. Removal of a heartworm via the femoral artery is extremely rare in veterinary medicine and has been reported on only a few occasions in dogs, but never in cats. Federal law restricts this drug to use by or on the order of a licensed veterinarian. PREVICOX firocoxib Chewable Tablets are indicated for the control of pain and inflammation associated with osteoarthritis and for the control of postoperative pain and inflammation associated with soft-tissue and orthopedic surgery in dogs. Not for use in humans. Keep this and all medications out of the reach of children. Consult a physician in case of accidental ingestion by humans. For oral use in dogs only. Use of this product at doses above the recommended 2. Due to tablet sizes and scoring, dogs weighing less than All dogs should undergo a thorough history and physical examination before the initiation of NSAID therapy. Appropriate laboratory testing to establish hematological and serum baseline data is recommended prior to and periodically during administration of any NSAID. For technical assistance or to report suspected adverse events, call This product cannot be accurately dosed in dogs less than As a class, cyclooxygenase inhibitory NSAIDs may be associated with renal, gastrointestinal and hepatic toxicity. Sensitivity to drug-associated adverse events varies with the individual patient. Concurrent administration of potentially nephrotoxic drugs should be carefully approached and monitored. NSAIDs may inhibit the prostaglandins that maintain normal homeostatic function. Such anti-prostaglandin effects may result in clinically significant disease in patients with underlying or pre-existing disease that has not been previously diagnosed. Commonly used protein-bound drugs include cardiac, anticonvulsant, and behavioral medications. Drug compatibility should be monitored in patients requiring adjunctive therapy. Appropriate monitoring procedures should be employed during all surgical procedures. Anesthetic drugs may affect renal perfusion, approach concomitant use of anesthetics and NSAIDs cautiously. The use of parenteral fluids during surgery should be considered to decrease potential renal complications when using NSAIDs perioperatively. The following adverse reactions were observed. Dogs may have experienced more than one of the observed adverse reactions during the study. Adverse Reactions Seen in U. In controlled field studies evaluating soft-tissue postoperative pain and inflammation, dogs ages Dogs may have experienced more than one of the observed reactions during the study. In a controlled field study evaluating orthopedic postoperative pain and inflammation, dogs of various breeds, ranging in age from 1 to The following adverse reactions are based on post-approval adverse drug event reporting. The categories are listed in decreasing order of frequency by body system: Vomiting, anorexia, diarrhea, melena, gastrointestinal perforation, hematemesis, hematachezia, weight loss, gastrointestinal ulceration, peritonitis, abdominal pain, hypersalivation, nausea Urinary: For a complete listing of adverse reactions for firocoxib reported to the CVM see: Owners should be advised of the potential for adverse reactions and be informed of the clinical signs associated with drug intolerance. Adverse reactions may include vomiting, diarrhea, decreased appetite, dark or tarry stools, increased water consumption, increased urination, pale gums due to anemia, yellowing of gums, skin or white of the eye due to jaundice, lethargy, incoordination, seizure, or behavioral changes. Serious adverse reactions associated with this drug class can occur without warning and in rare situations result in death see Adverse Reactions. The vast majority of patients with drug-related adverse reactions have recovered when the signs are recognized, the drug is withdrawn, and veterinary care, if appropriate, is initiated. Owners should be advised of the importance of

periodic follow up for all dogs during administration of any NSAID. Two hundred and forty-nine dogs of various breeds, ranging in age from 11 months to 20 years, and weighing 13 to lbs, were randomly administered PREVICOX or an active control drug in two field studies. Dogs were assessed for lameness, pain on manipulation, range of motion, joint swelling, and overall improvement in a non-inferiority evaluation of PREVICOX compared with the active control. Dogs treated with PREVICOX showed a level of improvement in veterinarian-assessed lameness, pain on palpation, range of motion, and owner-assessed improvement that was comparable to the active control. The level of improvement in PREVICOX-treated dogs in limb weight bearing on the force plate gait analysis assessment was comparable to the active control. In a separate field study, two hundred fifty-eight client-owned dogs of various breeds, ranging in age from The study demonstrated that PREVICOX-treated dogs had significantly lower need for rescue medication than the control sham-dosed-pilled in controlling postoperative pain and inflammation associated with soft-surgery. A multi-center field study with client-owned dogs of various breeds, and ranging in age from 1 to Dogs were randomly assigned to either the PREVICOX or the control sham-dosed-pilled group for the control of postoperative pain and inflammation associated with orthopedic surgery. Surgery to repair a ruptured cruciate ligament included the following stabilization procedures: Decreased appetite, vomiting, and diarrhea were seen in dogs in all dose groups, including unmedicated controls, although vomiting and diarrhea were seen more often in dogs in the 5X dose group. One dog in the 3X dose group was diagnosed with juvenile polyarteritis of unknown etiology after exhibiting recurrent episodes of vomiting and diarrhea, lethargy, pain, anorexia, ataxia, proprioceptive deficits, decreased albumin levels, decreased and then elevated platelet counts, increased bleeding times, and elevated liver enzymes. On histopathologic examination, a mild ileal ulcer was found in one 5X dog. This dog also had a decreased serum albumin which returned to normal by study completion. One control and three 5X dogs had focal areas of inflammation in the pylorus or small intestine. Vacuolization without inflammatory cell infiltrates was noted in the thalamic region of the brain in three control, one 3X, and three 5X dogs. Mean ALP was within the normal range for all groups but was greater in the 3X and 5X dose groups than in the control group. Transient decreases in serum albumin were seen in multiple animals in the 3X and 5X dose groups, and in one control animal. On histopathologic examination, one control, one 1X, and two 5X dogs had diffuse slight hepatic fatty change. These animals showed no clinical signs and had no liver enzyme elevations. In the 3X dose group, one dog was euthanized because of poor clinical condition Day This dog also had a mildly decreased serum albumin. At study completion, out of five surviving and clinically normal 3X dogs, three had minimal periportal hepatic fatty change. Of twelve dogs in the 5X dose group, one died Day 82 and three moribund dogs were euthanized Days 38, 78, and 79 because of anorexia, poor weight gain, depression, and in one dog, vomiting. One of the euthanized dogs had ingested a rope toy. Two of these 5X dogs had mildly elevated liver enzymes. At necropsy all five of the dogs that died or were euthanized had moderate periportal or severe panzonal hepatic fatty change; two had duodenal ulceration; and two had pancreatic edema. Of two other clinically normal 5X dogs out of four euthanized as comparators to the clinically affected dogs , one had slight and one had moderate periportal hepatic fatty change. Drug treatment was discontinued for four dogs in the 5X group. These dogs survived the remaining 14 weeks of the study. On average, the dogs in the 3X and 5X dose groups did not gain as much weight as control dogs. Rate of weight gain was measured instead of weight loss because these were young growing dogs. Thalamic vacuolation was seen in three of six dogs in the 3X dose group, five of twelve dogs in the 5X dose group, and to a lesser degree in two unmedicated controls. Diarrhea was seen in all dose groups, including unmedicated controls. All dogs survived to the end of the study. Three of the four treated dogs developed small intestinal erosion or ulceration. Treated dogs that developed small intestinal erosion or ulceration had a higher incidence of vomiting, diarrhea, and decreased food consumption than control dogs. One of these dogs had severe duodenal ulceration, with hepatic fatty change and associated vomiting, diarrhea, anorexia, weight loss, ketonuria, and mild elevations in AST and ALT. All four treated dogs exhibited progressively decreasing serum albumin that, with the exception of one dog that developed hypoalbuminemia, remained within normal range. Mild weight loss also occurred in the treated group. One of the two control dogs and three of the four treated dogs exhibited transient increases in ALP that remained within normal

range. Made in France Marketed by: It promotes prudent antimicrobial use among companion animal practitioners by contributing a baseline of antimicrobial usage data to the discussion on how to improve concordance with published guidelines. This article examines the issue of AMR within the larger One Health context and proposes a method by which to change behavior among hospital teams and drive quality improvement within the veterinary profession. Quality improvement developed as a science in the s. It began as a tool in the manufacturing industry, and its applicability to a variety of other situations, including healthcare, was quickly recognized. The Model for Improvement, developed by Associates in Process Improvement, guides application of key concepts of quality improvement to business challenges of many types. What are we trying to accomplish? To define the aim, the user must explicitly define what is to be accomplished and the timeframe in which it is to be achieved: How will we know that a change is an improvement? Objective measures are used to determine the point at which the goal has been reached. This requires data for baseline measurement and results to compare against. Many data sources can be used to measure antimicrobial guideline concordance, but all must be assessed for validity and accuracy to ensure appropriate interpretation. Examples include medical record reviews, logs of antimicrobial dispensing practices, case response logs, doctor surveys, or a combination of data. Assess percentage of cases that received recommended first-line antimicrobial. What changes can we make that will result in improvement?
